

METHANOL IN TRANSLUCENT INTERSTELLAR MOLECULAR CLOUDS

B.E. TURNER, *NRAO, 520 Edgemont Rd., Charlottesville, VA 22903, USA.*

We have detected several low-J lines of E- and A-type methanol in 17 translucent interstellar clouds whose physical conditions and chemistry have recently been well studied. The mean fractional abundance is $1(-8)$, similar to the abundance of $3(-9)$ found in cold dark clouds. Gas-phase formation occurs via $\text{CH}_3^+ + \text{H}_2\text{O} \rightarrow \text{CH}_3\text{OH}_2^+ + \text{h}\nu$. We have verified the predictions of this simple process by using the full Standard Model of interstellar chemistry (over 3000 reactions). While most interstellar molecules are formed by gas-phase processes, these models predict CH_3OH abundances 4 orders of magnitude less than the observed abundances. We have examined grain surface chemistry in which accreted CO hydrogenates to CH_3OH on the surface under the action of UV or cosmic rays, then desorbs principally by photodesorption. These processes can easily explain the observed CH_3OH abundances, and in fact imply lower desorption efficiencies than usually adopted.
