The near infrared electronic transition of CuCl occurring in the region of $13,500\text{ cm}^{-1}$ has been recorded by intracavity laser absorption spectroscopy. The CuCl molecules were produced in a copper hollow cathode operating with an applied potential of 700 V, using 1.4 torr argon and a trace amount of carbon tetrachloride.

The near infrared transition previously was recorded by Balfour and Ram,^a and it was assigned as emission from a low-lying $^3\Sigma^+$ state to the $X^1\Sigma^+$ state. Recently, this transition has received considerable attention because of high level *ab initio* calculations^b that question whether this transition involves the $X^1\Sigma^+$ ground state.
