HEGELUND, *Department of Chemistry, Aarhus University, Denmark.*

The microwave spectrum of 1,2,4-triazine has been recorded in the Ku- and Ka-bands using a conventional stark spectrometer. The low-J lines appeared close to the frequencies predicted for the ground state from the high resolution FTIR-studies^a, but to secure a correct assignment of higher J Q-branch transitions, a microwave-microwave double resonance experiment was done for a few pairs of transitions sharing a common level. 145 transitions were recorded with $J_{max} = 42$, $K_{a,max} = 33$, and $K_{c,max} = 11$. A simultaneous fit to MW pure rotational transitions and to the rotational structure of selected IR-bands led to a determination of rotational and all 5 quartic centrifugal distortion constants.
