Simultaneous transitions in IR absorption spectra of binary and ternary solutions with CO₂, CS₂, CHCl₃ and alcohols at high pressures and temperatures were measured. With the purpose of study of a degree of effect of pressure on a half-width and intensity in solutions of Raman spectra lines 606cm⁻¹ of benzene, 261cm⁻¹ of chloroform and their 90% solutions in cyclohexane were studied. In solutions the degree of reduction of a half-width of lines is little bit more than in pure liquids, in identical pressures range. We revealed the correlation of parameters of the simultaneous transition bands and Raman spectra.
