

INVESTIGATION OF THE LOW- n^* RYDBERG STATES OF CALCIUM MONOFLUORIDE NEAR
THE INTERSECTION WITH THE $^2\Sigma^+$ DISSOCIATIVE POTENTIAL

DANIEL S. BYUN, JEFFREY J. KAY, VLADIMIR S. PETROVIĆ, and ROBERT W. FIELD, *Department of
Chemistry, Massachusetts Institute of Technology, Cambridge, MA 02139.*

Previous work in our laboratory has shown that a single repulsive state (assigned as $^2\Sigma^+$) is responsible for predissociation of all $^2\Sigma^+$ Rydberg states of CaCl in the low- n^* region. The difference between the dissociation limit of CaCl and its first ionization potential is $15,500\text{ cm}^{-1}$ while the difference is only $2,800\text{ cm}^{-1}$ in CaF, suggesting that lower Rydberg states in CaF will not be as extensively predissociated. However, we have recently observed significant predissociation in CaF. The double resonance spectra of the low- n^* ($n^*=5-7$) Rydberg states of CaF have been reinvestigated in an attempt to characterize the repulsive $^2\Sigma^+$ state responsible for the predissociation in CaF.
